

Department : Mathematics and Computer Science
 Level : Third
 Course Code : 040101309
 Course Title : Integral Equations
 Semester : Fall 2024
 Time Allowed : 30 minutes
 Lecturer : Dr.Hanna R. Ebead
 Total Marks : 30 Points

Mid-Term Examination-Model Answer

Question 1: (a)

Using *Successive Approximation Method*

Let initial guess $y_0(t) = x$ Then

$$\begin{aligned}
 y_1(t) &= x - \int_0^x (x-t)t \, dt = x - \frac{x^3}{3!} \\
 y_2(t) &= x - \int_0^x (x-t)\left(t - \frac{t^3}{3!}\right) dt = x - \frac{x^3}{3!} + \frac{x^5}{5!} \\
 y_3(t) &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} \\
 &\vdots \\
 y_n(t) &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \\
 &= \sum_{k=1}^n \frac{(-1)^{k-1} x^{2k+1}}{(2k+1)!}
 \end{aligned}$$

Since $y(x) = \lim_{n \rightarrow \infty} y_n(t)$ we deduce that

$$\begin{aligned}
 y_n(t) &= \lim_{n \rightarrow \infty} \sum_{k=1}^n \frac{(-1)^{n-1} x^{2n+1}}{(2n+1)!} \\
 &= \sum_{k=1}^{\infty} \frac{(-1)^{n-1} x^{2n+1}}{(2n+1)!} = \sin(x)
 \end{aligned}$$

Question 1: (b)

Since, $k(t, s) = ts$ separable, we can use *Direct Computational Method*

$$y(t) = \frac{7}{8}t + \frac{1}{2}t \int_0^1 tsy^2(s) \, ds$$

$$\text{Let } C = \int_0^1 sy^2(s) \, ds$$

$$\begin{aligned}
 y(t) &= \frac{7}{8}t + \frac{1}{2}tC \\
 C &= \int_0^1 s \left[\frac{7}{8}s + \frac{1}{2}sC \right]^2 ds \\
 C &= \int_0^1 s^3 \left[\frac{7}{8} + \frac{1}{2}C \right]^2 ds = \frac{1}{4} \left[\frac{7}{8} + \frac{1}{2}C \right]^2
 \end{aligned}$$

$$16C^2 - 200C + 49 = 0$$

We get two solutions

$$\begin{cases} y_1(t) = 7tAtC_1 = \frac{49}{4} \\ y_2(t) = tAtC_2 = \frac{1}{4} \end{cases}$$

Question 2: (a)

Since $k(t, s)$ is continuous on closed domain $[a, b] \times [a, b]$. so it guarantees the existence of a finite $L > 0$

From *Existence and uniqueness theorem* we are able to prove that the integral equation has a unique continuous solution $y \in C[a, b]$

Since $f, k(t, \cdot) \in C[a, b] \subset L_2[a, b] \quad t \in [a, b]$

Then $M = \int_a^b \int_a^b |k(t, s)|^2 ds dt \leq \int_a^b \int_a^b L^2 ds dt = L^2(b-a)^2$

$$\sqrt{M} \leq L(b-a)$$

Thus, we deduce that

$$|\lambda| < \frac{1}{L(b-a)}$$

Question 2: (b)

Consider the integral equation

$$y(t) = -4 + \int_0^1 (2t + 3s)y(s) ds \quad t \in [0, 1]$$

We have $\lambda = 1$, $L = \max_{t, s \in [a, b] \times [a, b]} |2t + 3s| = 5$, $b - a = 1$ which means that it

doesn't satisfy the theorem because $|\lambda| < \frac{1}{L(b-a)}$ doesn't hold

But the equation has a solution given by $y(t) = 4t$

Question 3:

Let y solves the IVP.

Integrate the equation from $0 \rightarrow x$

$$\int_0^x y'' dt - 2 \underbrace{\int_0^x ty' dt}_J - 3 \int_0^x y dt = 0 \quad (1)$$

Using integration by parts on J we get

$$\begin{aligned} J &= \int_0^x ty' dt = [ty]_0^x - \int_0^x y dt \\ &= xy(x) - \int_0^x y dt \end{aligned}$$

Substitute in (1)

$$\begin{aligned} y'(x) - y'(0) - 2xy(x) + 2 \int_0^x y dt - 3 \int_0^x y dt &= 0 \\ y'(x) - 2xy(x) - \int_0^x y dt &= 0 \end{aligned} \quad (2)$$

Integrate (2) from $0 \rightarrow x$

$$y(x) - y(0) - 2 \int_0^x t y(t) dt - \int_0^x \int_0^\xi y(t) dt d\xi = 0$$

$$y(x) = 1 + 2 \int_0^x t y(t) dt + \int_0^x \int_t^x y(t) d\xi dt$$

$$y(x) = 1 + 2 \int_0^x t y(t) dt + \int_0^x (x - t) y(t) dt$$

$$y(x) = 1 + \int_0^x (x + t) y(t) dt$$
